## Developmental neurotoxicity of industrial chemicals

P Grandjean, P J Landrigan

Neurodevelopmental disorders such as autism, attention deficit disorder, mental retardation, and cerebral palsy are common, costly, and can cause lifelong disability. Their causes are mostly unknown. A few industrial chemicals (eg, lead, methylmercury, polychlorinated biphenyls [PCBs], arsenic, and toluene) are recognised causes of neurodevelopmental disorders and subclinical brain dysfunction. Exposure to these chemicals during early fetal development can cause brain injury at doses much lower than those affecting adult brain function. Recognition of these risks has led to evidence-based programmes of prevention such as elimination of lead additives in petrol. Although these prevention campaigns are highly successful, most were initiated only after substantial delays. Another 200 chemicals are known to cause clinical neurotoxic effects in adults. Despite an absence of systematic testing, many additional chemicals have been shown to be neurotoxic in laboratory models. The toxic effects of such chemicals in the developing human brain are not known and they are not regulated to protect children. The two main impediments to prevention of neurodevelopmental deficits of chemical origin are the great gaps in testing chemicals for developmental neurotoxicity and the high level of proof required for regulation. New, precautionary approaches that recognise the unique vulnerability of the developing brain are needed for testing and control of chemicals.

A few industrial chemicals (eg, **lead, methylmercury, polychlorinated biphenyls [PCBs], arsenic**, and **toluene**) were recognized causes of neurodevelopmental disorders and subclinical brain dysfunction.

Twelve years ago two well-known experts in *Environmental Health*, a pediatrician and an epidemiologist, launched an alarm from the pages of ***the Lancet***, affirming that a ***silent pandemic* of neurodevelopmental disorders** was spreading, also due to the *shortage of funds in this area of research*

**In fact the reports of autism cases per 1,000 children had increased dramatically over the years in the U.S. from 1996 to 2007**

# autism the great modern health concern

CDC Centers for Disease Control and Prevention

**Autism spectrum disorders** (**ASDs**) are a group of developmental disabilities that can cause significant social, communication and behavioral challenges. People with **ASDs** handle information in their brain differently than other people. **ASDs** are "spectrum disorders." That means **ASDs** affect each person in different ways, and can range from very mild to severe. There are three different types of **ASDs**: **Autistic Disorder** (also called "classic" autism), **Asperger Syndrome** and **Pervasive Developmental Disorder** – Not Otherwise Specified (PDD-NOS; also called "atypical autism")

**1980 1 : 1500**

## Autistic Disorder

What most people think of when hearing the word "autism." People with autistic disorder usually have significant language delays, social and communication challenges and unusual behaviors and interests.

## Asperger Syndrome

Usually have some milder symptoms of autistic disorder. They might have social challenges and unusual behaviors and interests. However, typically do not have problems with language or intellectual disability.

## Pervasive Developmental Disorder

The symptoms might cause only social and communication challenges. People with PDD-NOS usually have fewer and milder symptoms than those with autistic disorder.

**2002 1 : 150**

**1 in 150** children in the US have an ASD CDC estimated average

meaning

**1%** of the population of children aged 3-17 have an ASD

**2014 1 : 68**

with

ASDs 4 to 7 times more likely to occur in BOYS than in GIRLS

**2006 1 : 110**

There is no medical test to diagnose ASDs, doctors look at the child's behavior and development to make a diagnosis.

About half of parents of children with ASD notice their child's unusual behaviors by age 18 months

about four-fifths notice by age 24 months

A person with an ASD might: Not respond to their name by 12 months | Avoid eye contact and want to be alone | Have delayed speech and language skills | Repeat words or phrases over and over (echolalia) | Give unrelated answers to questions | Get upset by minor changes

**2008 1 : 88**

ASDs are the fastest-growing developmental disability **1,148%** growth rate with **10-17%** annual growth

Reports of autism cases per 1,000 children

Lifetime cost to care for an individual with an ASD Estimated from recent studies **$3.2m** with **$4,110–$6,200 per year** of medical expenditures for an individual with an ASD than one without

Neurodevelopmental disabilities, including autism, attention-deficit hyperactivity disorder, dyslexia, and other cognitive impairments, affect millions of children worldwide, and some diagnoses seem to be increasing in frequency. Industrial chemicals that injure the developing brain are among the known causes for this rise in prevalence. In 2006, we did a systematic review and identified five industrial chemicals as developmental neurotoxicants: lead, methylmercury, polychlorinated biphenyls, arsenic, and toluene. Since 2006, epidemiological studies have documented six additional developmental neurotoxicants—manganese, fluoride, chlorpyrifos, dichlorodiphenyltrichloroethane, tetrachloroethylene, and the polybrominated diphenyl ethers. We postulate that even more neurotoxicants remain undiscovered. To control the pandemic of developmental neurotoxicity, we propose a global prevention strategy. Untested chemicals should not be presumed to be safe to brain development, and chemicals in existing use and all new chemicals must therefore be tested for developmental neurotoxicity. To coordinate these efforts and to accelerate translation of science into prevention, we propose the urgent formation of a new international clearinghouse.

The same two authors returned to the problem **seven years later, with a broad review published the Lancet Neurology (2014)**

**Since 2006**, epidemiological studies have documented **six additional developmental neurotoxicants — manganese, fluoride, chlorpyrifos, tetrachloroethylene, dichlorodiphenyltrichloroethane, and the polybrominated diphenyl ethers.**
We postulate that even more neurotoxicants remain undiscovered

Community Report from the
**Autism and Developmental Disabilities Monitoring (ADDM) Network**

ADDM Network

**1.7%**
is the average percentage identified with ASD

**1 in 59**
8-year-old children were identified with ASD by ADDM in 2014

## Why is this information important and how can it be used?

1. Lower the age of first evaluation by community providers and
2. Increase awareness of ASD among black and Hispanic families, and identify and address barriers in order to ensure that all children with ASD are evaluated, diagnosed, and connected to services.

PEDIATRICS
OFFICIAL JOURNAL OF THE AMERICAN ACADEMY OF PEDIATRICS

# The Prevalence of Parent-Reported Autism Spectrum Disorder Among US Children

Michael D. Kogan, PhD,[a] Catherine J. Vladutiu, PhD, MPH,[a] Laura A. Schieve, PhD,[b] Reem M. Ghandour, DrPH,[a] Stephen J. Blumberg, PhD,[c] Benjamin Zablotsky, PhD,[c] James M. Perrin, MD,[d] Paul Shattuck, PhD,[e] Karen A. Kuhlthau, PhD,[d] Robin L. Harwood, PhD,[a] Michael C. Lu, MD, MPH[f]

**OBJECTIVES:** To estimate the national prevalence of parent-reported autism spectrum disorder (ASD) diagnosis among US children aged 3 to 17 years as well as their treatment and health care experiences using the 2016 National Survey of Children's Health (NSCH).

**METHODS:** The 2016 NSCH is a nationally representative survey of 50 212 children focused on the health and well-being of children aged 0 to 17 years. The NSCH collected parent-reported information on whether children ever received an ASD diagnosis by a care provider, current ASD status, health care use, access and challenges, and methods of treatment. We calculated weighted prevalence estimates of ASD, compared health care experiences of children with ASD to other children, and examined factors associated with increased likelihood of medication and behavioral treatment.

**RESULTS:** Parents of an estimated 1.5 million US children aged 3 to 17 years (2.50%) reported that their child had ever received an ASD diagnosis and currently had the condition.

**CONCLUSIONS:** The estimated prevalence of US children with a parent-reported ASD diagnosis is now 1 in 40, with rates of ASD-specific treatment usage varying by children's sociodemographic and co-occurring conditions.

# New genetic risk factor for developing autism spectrum disorder identified

**Autism risk due to unexpected mosaic mutations**

*Date:* August 31, 2017

*Source:* Oregon Health & Science University

*Summary:* A new systematic analysis has been applied to a cohort of 2,300 families who have a single child affected with autism. The study focused on identifying and characterizing low-lying genetic mutations that may have been missed in previous research, given these mutations are only present in a fraction of the bulk DNA of an individual.

tematic analysis to a cohort of 2,300 families who have a single child affected with autism. The study focused on identifying and characterizing low-lying genetic mutations that may have been missed in previous research, given these mutations are only present in a fraction of the bulk DNA of an individual.

Known as postzygotic mosaic mutations, or PMMs, these genetic changes occur after the conception of the human zygote during the development cycle of a fetus. An individual will contain a mosaic -- or assortment -- of mutated and non-mutated cells with the level of mosaicism depending on the time and location of the mutation's occurrence. This emerging class of genetic risk factors has recently been implicated in various neurologic conditions, however,

.. yet many continue **to define autism (and schizophrenia) as "genetic" diseases !!??!!**

As in this case: ***The risk of autism connected to unexpected exonic mutations ...!!??!!***

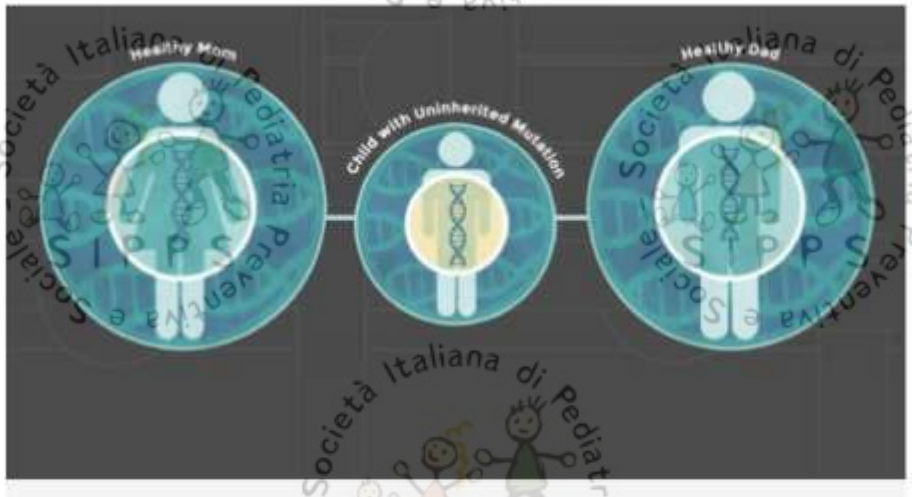
Darnell, Evan E. Eichler. **Genomic Patterns of De Novo Mutation in Simplex Autism**. *Cell*, 2017; DOI: 10.1016/j.cell.2017.08.047

# Autism genetics study calls attention to motor skills, general cognitive impairment

*Date:* February 7, 2018

*Source:* Cold Spring Harbor Laboratory

*Summary:* A new study of the genetic factors involved in the causation of autism spectrum disorders (ASD) draws fresh attention to the impact these illnesses have on motor skills, and more broadly on cognitive function. Careful inference from the data suggests to researchers that the genetic factors causing ASD broadly diminish the brain's cognitive functions.



Mutations that appear in a child which are not present in either parent -- called de novo mutations -- can be important in autism. Severe, gene-disrupting de novo mutations are thought to be capable of causing the disorder in certain instances. New research shows that diminished motor skills, like low non-verbal IQ, correlate with the severity of de novo mutations. More broadly the study calls attention to role played by genetics in di-

…or in this case: **new mutations disturbing motor functions** could be important in ***autism*** **...!!??!!**

**IMPORTANCE** The origins and development of autism spectrum disorder (ASD) remain unresolved. No individual-level study has provided estimates of additive genetic, maternal, and environmental effects in ASD across several countries.

**OBJECTIVE** To estimate the additive genetic, maternal, and environmental effects in ASD.

**DESIGN, SETTING, AND PARTICIPANTS** Population-based, multinational cohort study including full birth cohorts of children from Denmark, Finland, Sweden, Israel, and Western Australia born between January 1, 1998, and December 31, 2011, and followed up to age 16 years. Data were analyzed from September 23, 2016 through February 4, 2018.

**MAIN OUTCOMES AND MEASURES** Across 5 countries, models were fitted to estimate variance components describing the total variance in risk for ASD occurrence owing to additive genetics, maternal, and shared and nonshared environmental effects.

**RESULTS** The analytic sample included 2 001 631 individuals, of whom 1 027 546 (51.3%) were male. Among the entire sample, 22 156 were diagnosed with ASD. The median (95% CI) ASD heritability was 80.8% (73.2%-85.5%) for country-specific point estimates, ranging from 50.9% (25.1%-75.5%) (Finland) to 86.8% (69.8%-100.0%) (Israel). For the Nordic countries combined, heritability estimates ranged from 81.2% (73.9%-85.3%) to 82.7% (79.1%-86.0%). Maternal effect was estimated to range from 0.4% to 1.6%. Estimates of genetic, maternal, and environmental effects for autistic disorder were similar with ASD.

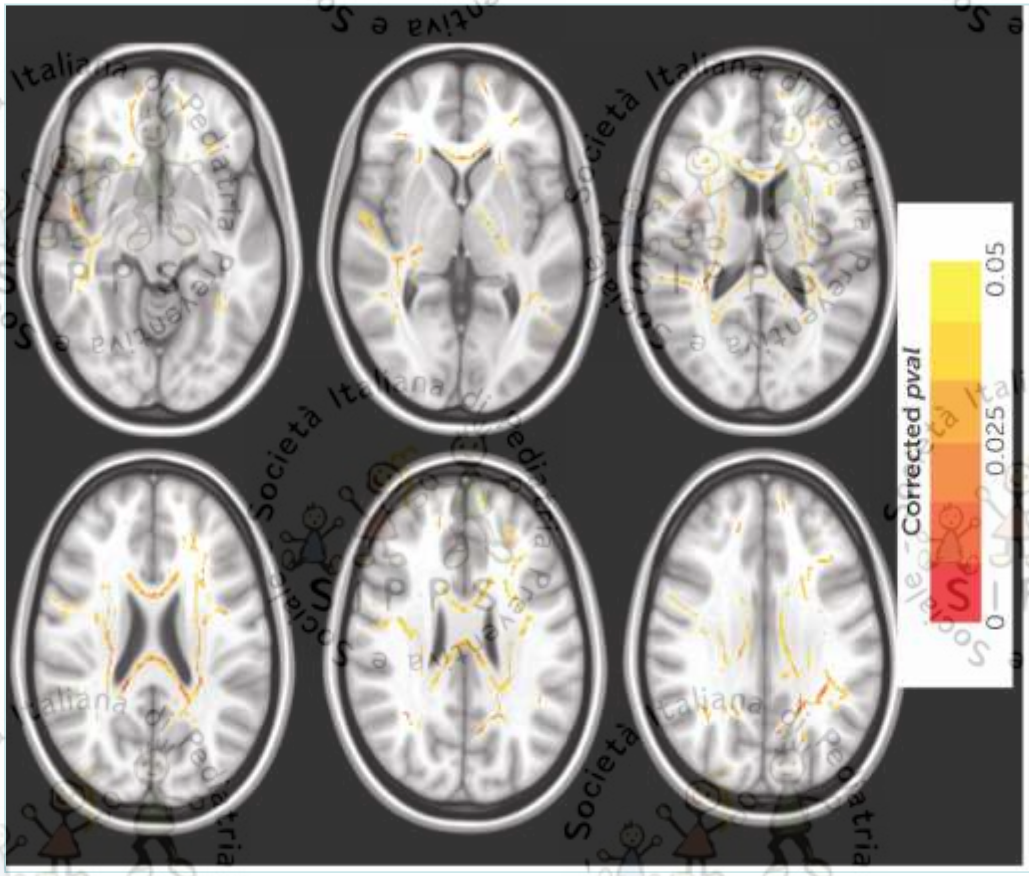
**CONCLUSIONS AND RELEVANCE** Based on population data from 5 countries, the heritability of ASD was estimated to be approximately 80%, indicating that the variation in ASD occurrence in the population is mostly owing to inherited genetic influences, with no support for contribution from maternal effects. The results suggest possible modest differences in the sources of ASD risk between countries.

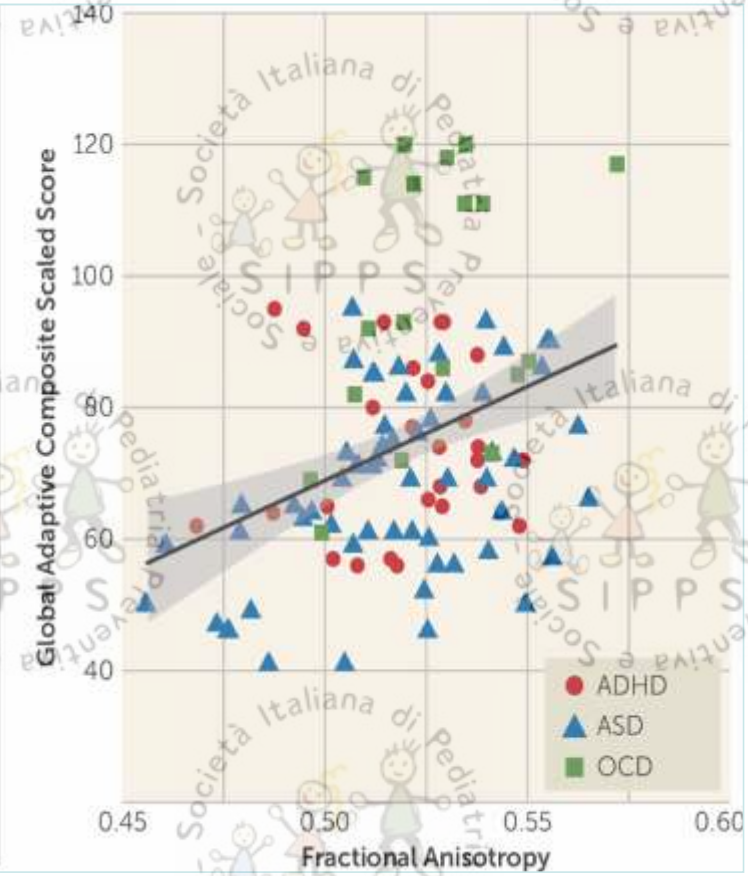
***Heritability*** estimates ranged from **81.2%**(73.9%-85.3%) to 82.7% (79.1%- 86.0%). ***Maternal effect*** was estimated to range from ***0.4% to 1.6%.***

**Autism, ADHD** and **OCD** have **common symptoms** and **are linked by some of the same genes**.

**Yet they have always been considered as separate disorders**

***a continuum...***





Children with autism and ADHD showed more severe impairments affecting more of the brain's white matter than those with OCD. This finding may reflect the fact that both autism and ADHD typically have an onset at a much younger age than OCD, and at a time when a number of different white matter tracts are going through rapid development,

# Environment and fetal programming: the origins of some current "pandemics"

**Ernesto Burgio**

ECERI – European Cancer and Environment Institute, Bruxelles, Belgium
ISDE – International Society of Doctors for Environment (Scientific Office), Arezzo, Italy

This new paradigm is important not only to explain in a more exhaustive way the embryo-foetal origins of all the above mentioned disorders and their dramatic increase over the last decades, but also to try to effectively face this epidemiological transition. The key-term in this context is certainly primary prevention: only by reducing the maternal-foetal factors of distress and the exposure of the foetus (and of its gametes) to pollutants, it would be possible to protect the correct programming of cells, tissues and organs.

The key-term in this context is certainly ***primary prevention***

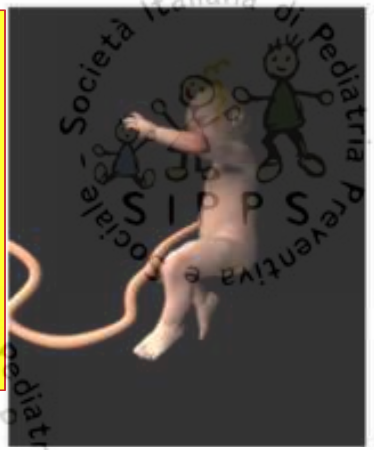
## Le placenta transmet les pesticides au fœtus

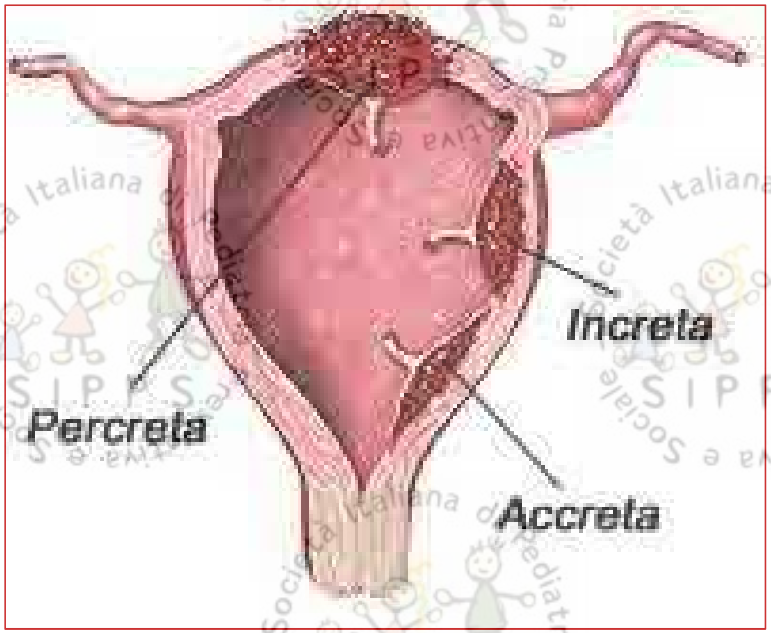
***L'incidence des allergies comme l'asthme a augmenté au cours des dernières décennies. Dans le cadre des efforts menés pour en trouver la raison, les scientifiques ont étudié le transport des composés chimiques à travers le placenta, du milieu environnant vers le fœtus.***

This is an **official website of the European Community** that lists many studies related to the problem of **maternal-fetal exposure to pollutants** and **toxics** (in particular to ***pesticides***): scientists found that **all xenobiotics cross the placental barrier by passive diffusion and reach the fetus**..... In the main fetal organs (especially in the blood, spleen, bone marrow, brain and liver) **the concentration of these pesticides is higher than in the corresponding maternal organs**. The implications are of great significance: the **accumulation of these compounds in the fetal tissues will have an impact on the development of the child's immune and nervous systems**



## 1 In fact **placental alterations** are more and more frequent

The ***placenta accreta*** is an insertion/invasion of/by the placenta **into maternal tissues**: there are three types according to the **insertion depth into the endo/myometrium**
- the proper placenta accreta : the villi penetrate more or less deeply into the myometrium;
- the placenta ***increta***: the villi invade the whole myometrium;
- the placenta ***percreta***: the villi go beyond the myometrium, sometimes **invading neighboring organs (bladder)** ...



... it is, in fact, ***as if the (immunological) mechanisms of maternal-fetal tolerance were weakening !***
... we must not forget that the placenta is largely **an embryo-fetal organ** (that the **embryo** himself produces **to connect** to the mother to get oxygen, nutrition, **information**... certainly not to invade her)

(***evolutionary mechanisms*** that are **millions of years old**)

**Choriocarcinoma**

2

... even more common all over the world has become **prematurity (today one child out of 10 is born prematurely** ... which represents **an increase of 30% over the last 35 years** ....) .. **another symptom of growing maternal-fetal intolerance** that should not be underestimated..

L'INSERM today defines different stages of prematurity:
**extremely preterm (less than 28 weeks)**
very preterm (28 to 32 weeks)
moderate to late preterm (32 to 37 weeks).

## Épidémiologie [ modifier | modifier le code ]

En 2012, plus d'un bébé sur dix naît prématurément dans le monde[5] sans évidence de décroissance avec le temps[6].

Les naissances prématurées concernent 11 à 13 % des naissances aux États-Unis, soit près du double du taux des autres pays industrialisés et une augmentation de 30 % par rapport à 1981[7]. Plus du quart des décès néonataux seraient la conséquence de la prématurité[8].

Les données sont probablement assez solides et permettent d'avoir aujourd'hui un aperçu évolutif concernant les trois dernières décennies en France.

**Évolution des taux d'incidence de la prématurité en France**

| | 1972 | 1981 | 1988 | 1995 | 2003 |
|---|---|---|---|---|---|
| **Très grande prématurité (de 22 à 27 SA)** | - | - | - | 0,4 % | 0,5 % |
| **Grande prématurité (de 28 à 32 SA)** | 1,3 % | - | 1 % | 1,2 % | 1,3 % |
| **Prématurité (de 33 à 37 SA)** | 8,2 % | 5,7 % | 4,8 % | 5,9 % | 7,2 % |

L'incidence est donc en augmentation, ce que confirme les chiffres d'autres pays, en particulier américains[7].

## Abstract

Over the past quarter century it has become clear that adult onset chronic diseases like heart disease and type 2 diabetes have their roots in early development. The report by David Barker and colleagues showing an inverse relationship between birthweight and mortality from ischemic heart disease was the first clear-cut demonstration of fetal programming. Because fetal growth depends upon the placental capacity to transport nutrients from maternal blood, it has been a suspected causative agent since the original Barker reports. Epidemiological studies have shown that placental size and shape have powerful associations with offspring disease. More recent studies have shown that maternal phenotypic characteristics, such as body mass index and height, interact with placental size and shape to predict disease with much more precision than does birthweight alone. For example, among people in the Helsinki Birth Cohort, who were born during 1924–1944, the risk for acquiring colorectal cancer increased as the placental surface became longer and more oval. Among people in whom the difference between the length and breadth of the surface exceeded 6 cm, the hazard ratio for the cancer was 2.3 (95% CI 1.2–4.7, p=0.003) compared with those in whom there was no difference. Among Finnish men, the hazard ratio for coronary heart disease was 1.07 (1.02–1.13, P =0.01) per 1% increase in the placental weight/birthweight ratio. Thus, it appears that the ratio of birthweight to placental weight, known as placental efficiency, predicts cardiovascular risk as well. Babies born with placentas at the extremes of efficiency are more vulnerable for adult onset chronic diseases. Recent evidence suggests that placental growth patterns are sex specific. Boys' placentas are, in general, more efficient than those made by girls. Another recent discovery is that the size, shape and efficiencies of the placenta can change over years of time with very narrow confidence limits. This suggests that the growth of the placenta within a population of women is strongly affected by their nutritional environment. Even though it

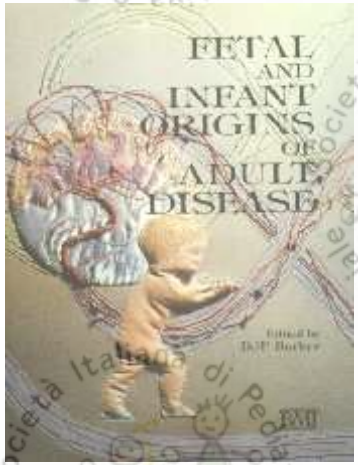
**ONTOGENY**

1 … a technical term that refers to the ***capability*** and, at the same time, the ***requirement***, for **embryo-foetal cells to define their epigenetic setting in a predictive and adaptive way** , in relation to the information coming from the mother and, through her, from the outer world ..

A ***predictive adaptive response (PAR)*** is a developmental trajectory taken by an organism during a period of ***developmental plasticity*** in response to perceived environmental cues..



2 FIG. 1. The fetus is particularly vulnerable to changes in the external and internal environments, which interact to influence fetal development and have both immediate and life-long consequences. Such environmentally induced changes can occur at all levels of biological organization, from the molecular to the organism's behavior and place in society, and tend to be amplified in their consequences as they ascend through these levels. Ultimately, these influences may be epigenetic in nature, inducing mitotically heritable alterations in gene expression without changing the DNA.

3

The **fourth** keyword is ***developmental plasticity***

## *Cellular Differentiation*: an *epigentic process*

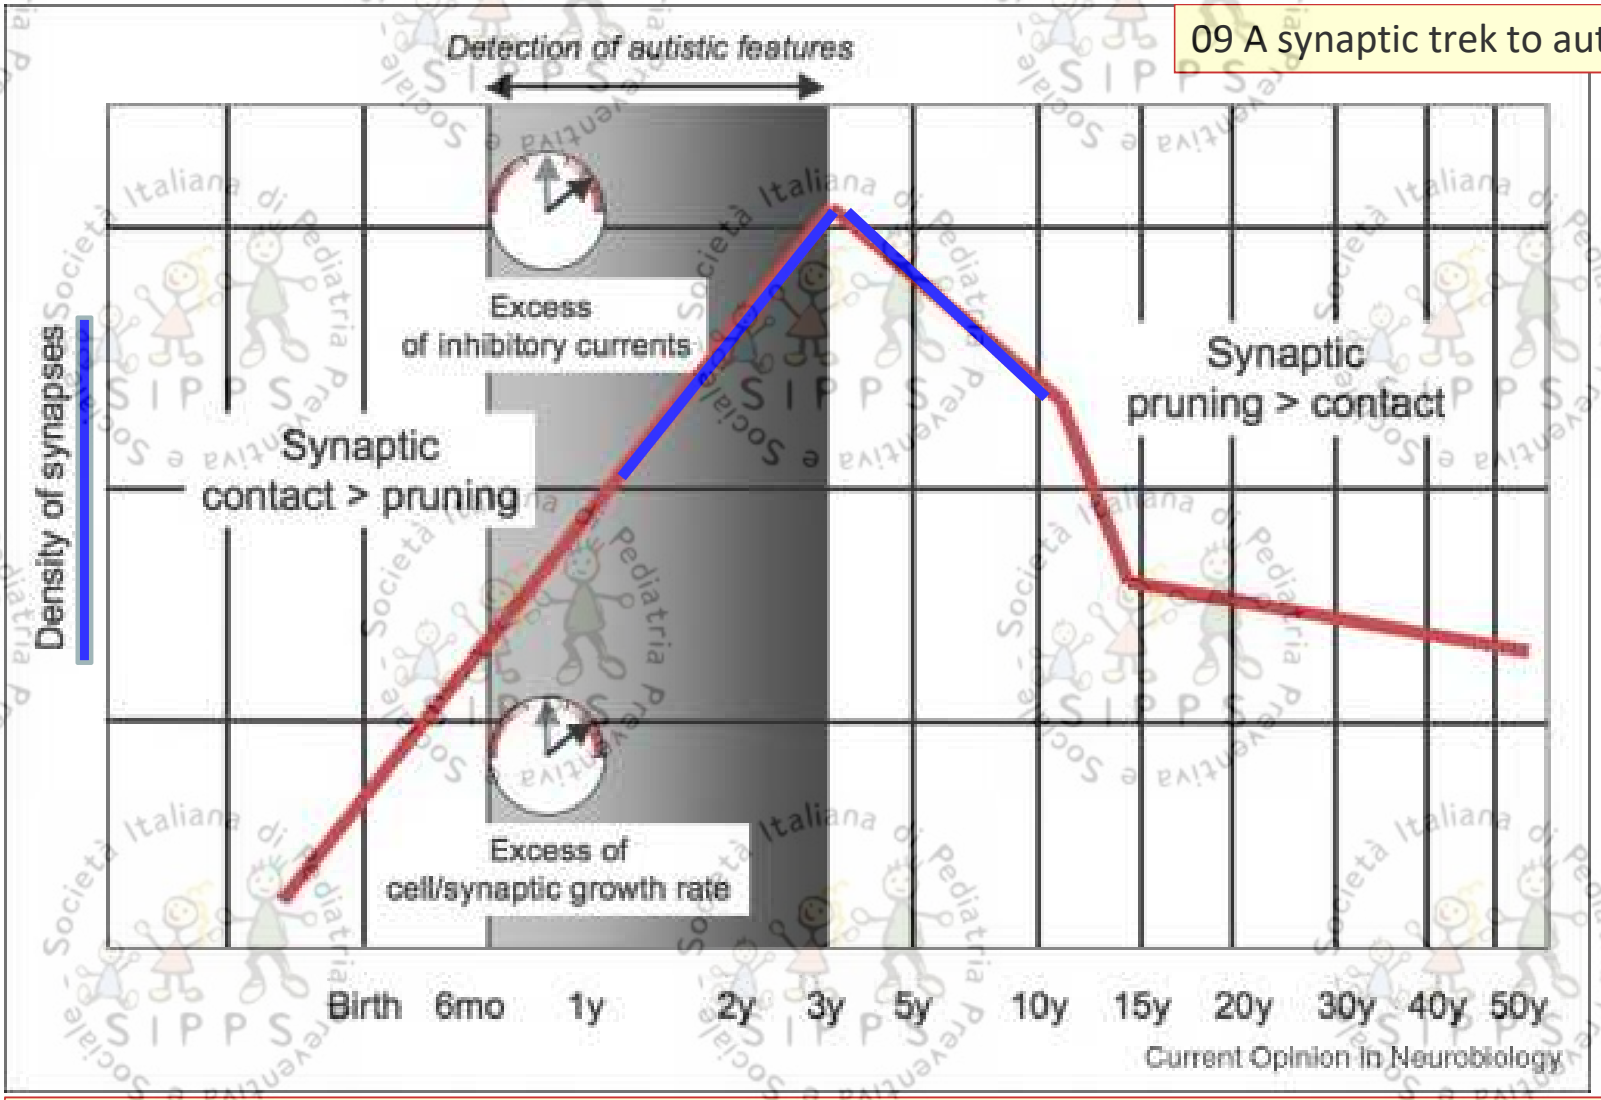
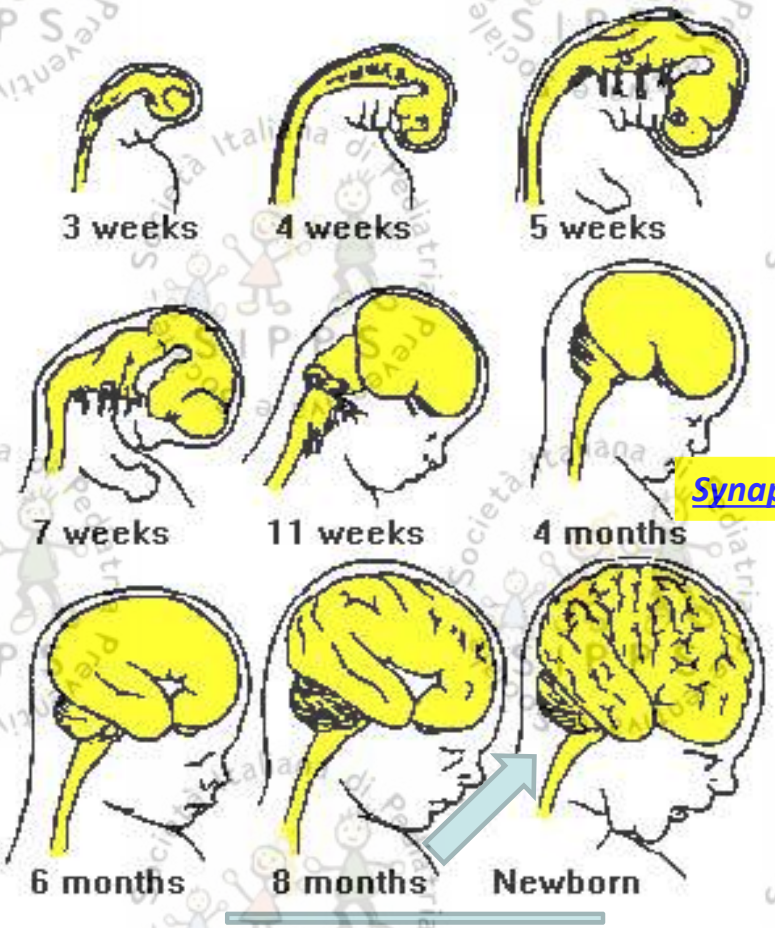
09 A synaptic trek to autism



Schematic representation of the **different phases of synaptogenesis** in the human brain.
**During the first three years of life, an excess of cell/synaptic growth rate and inhibitory currents could increase the risk of ASD.**



***Synaptogenesis***

The brain grows at an amazing rate during development.
At times during brain development, **250,000 neurons are added every minute!**
**At birth,** almost all the neurons that the brain will ever have are present.

However, the brain continues to grow for many years after birth.

**By the age of 2 years** old, the brain is about **80% of the adult size**

A **stegosaurus dinosaur weighed approximately 1,600 kg but had a brain that weighed only approximately 70 grams (0.07 kg).** Therefore, **the brain was only 0.004% of its total body** weight. In contrast, an adult human weighs approximately 70 kg and has a brain that weighs approximately 1.4 kg. Therefore, **the human brain is about 2% of the total body weight**. This makes the brain to body ratio of the human **500 times greater than that of the stegosaurus**

# Maternal Factors that Induce Epigenetic Changes Contribute to Neurological Disorders in Offspring

Avijit Banik [1], Deepika Kandilya [1], Seshadri Ramya [1], Walter Stünkel [2], Yap Seng Chong [3] and S. Thameem Dheen [1,*]

It is well established that **the regulation of epigenetic factors**, including **chromatin reorganization, histone modifications, DNA methylation, and miRNA regulation, is critical for the normal development and functioning of the human brain**.
There are a number of **maternal factors influencing epigenetic pathways such as lifestyle, including diet, alcohol consumption, and smoking**, as well as **age and infections** (viral or bacterial).

Genetic and metabolic alterations such as **obesity, gestational diabetes mellitus (GDM), and thyroidism alter epigenetic mechanisms, thereby contributing to neurodevelopmental disorders (NDs) such as embryonic neural tube defects (NTDs), autism, Down's syndrome, Rett syndrome, and later onset of neuropsychological deficits**.

This review comprehensively describes the recent findings in the epigenetic landscape contributing to altered molecular profiles resulting in NDs. Furthermore, we will discuss potential avenues for future **research to identify diagnostic markers and therapeutic epi-drugs to reverse these abnormalities in the brain as epigenetic marks are plastic and reversible in nature.**

**Figure 1 Smoking in mothers alters neurodevelopmental processes in the fetus. Maternal smoking alters the DNA methylation of genes involved in placental and fetal development, leading to neurodevelopmental disorders** in the offspring.

### Phenotypic outcomes in the offspring

**Fetal alcohol spectrum disorder (FASD)**

- Attention and memory deficit
- Craniofacial malformation
- Motor function abnormalities
- Auditory and language problem

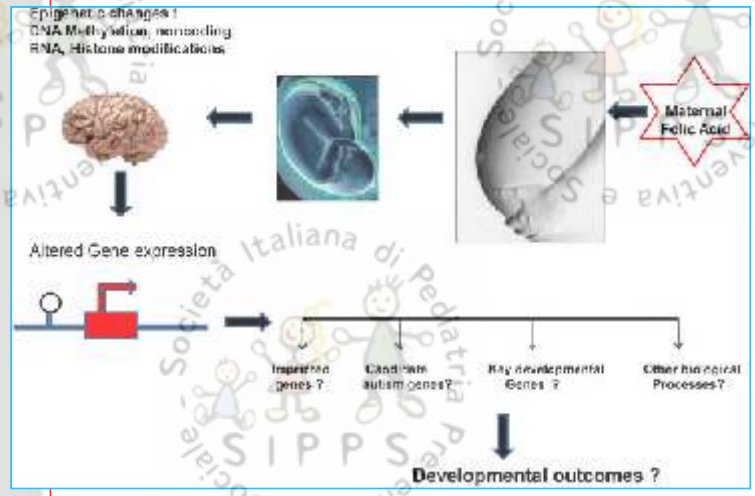
**F3** Effect of **maternal dietary deficiency** on fetal development.
**The absence of essential dietary supplements in maternal diet during gestation leads to a disruption in metabolic pathways and several epigenetic alterations in the fetus**, triggering **abnormal uterine development** and **neurodevelopmental disorders**.

## Maternal dietary deficiency

Absence of dietary methyl group donors such as folate, choline, methionine, betain and methylcobalamine

- Imbalance in folate-mediated one-carbon metabolism (FOCM) pathway [98]
- Mutation in methionine synthase reductase (*Mtrr*) gene, essential for deployment of methyl groups from the folate cycle [104]
- Down-regulation of genes related to fetal brain development: *BDNF*, *CREB*, *NGF* and *TrkB* [105]
- H3K9 and H4K20 methylation [114]
- Altered expression of miRNAs linked to FOCM pathway : miR-29c, miR-183, miR-422b, miR-189 [115]; miR-22, miR-24, miR-29b, miR-34a, miR-125, miR-344-5p/484, miR-488 [116-118]

Abnormal uterine development and congenital malformation [104]



**F4** Effect of **maternal metabolic conditions** on fetal development.
**Metabolic conditions at gestation such as GDM, obesity, and hypothyroidism induce epigenetic alterations in the fetus**, leading to a series of **metabolic and immunogenic changes triggering neuroanatomical and neuropsychological deficits in the developing brain**.

**Maternal metabolic conditions**

- Gestational Diabetes Mellitus (GDM)
- Maternal Obesity
- Maternal Hypothyroidism

Trigger epigenetic imbalance in the fetus [149,150,157,158,172]

- Induces oxidative stress [148]
- ROS accumulation [148]
- Inflammatory response [155]
- Cytokine production [156]
- Decreased T3 levels [169]
- Altered levels of metabolic genes [172]

Giuseppe Giordano ISDE

"Tobacco smoke is without a doubt the most significant environmental contaminant to which children are exposed indoors"

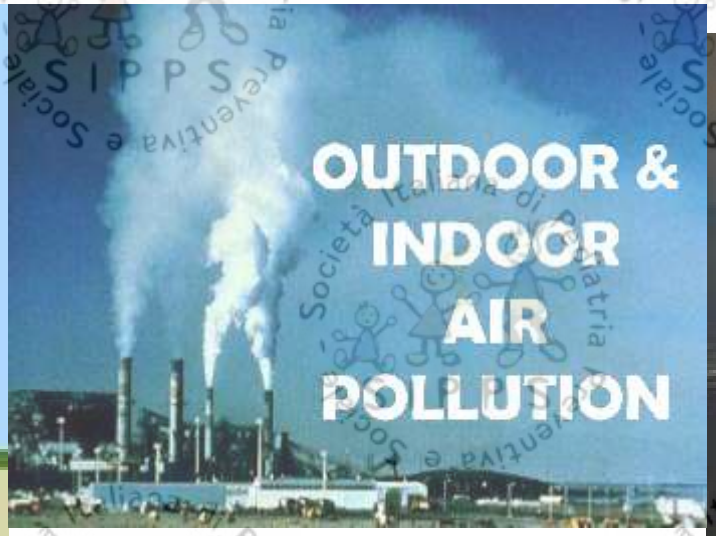
## Environmental tobacco smoke (ETS)

- Sudden infant death syndrome
- Lower respiratory tract illness
- Middle ear disease
- Asthma
- 12 million children exposed to secondhand smoke in homes

- Exposure to environmental tobacco smoke (ETS) causes more than 35,000 deaths annually among non-smokers.
- Smoking by pregnant women is responsible for about 1000 infant deaths each year in the U.S.
- Children exposed to ETS suffer higher rates of asthma, bronchitis, and pneumonia.
- Smokeless tobacco use has tripled since 1972, and cigar use has increased 50% since 1993.

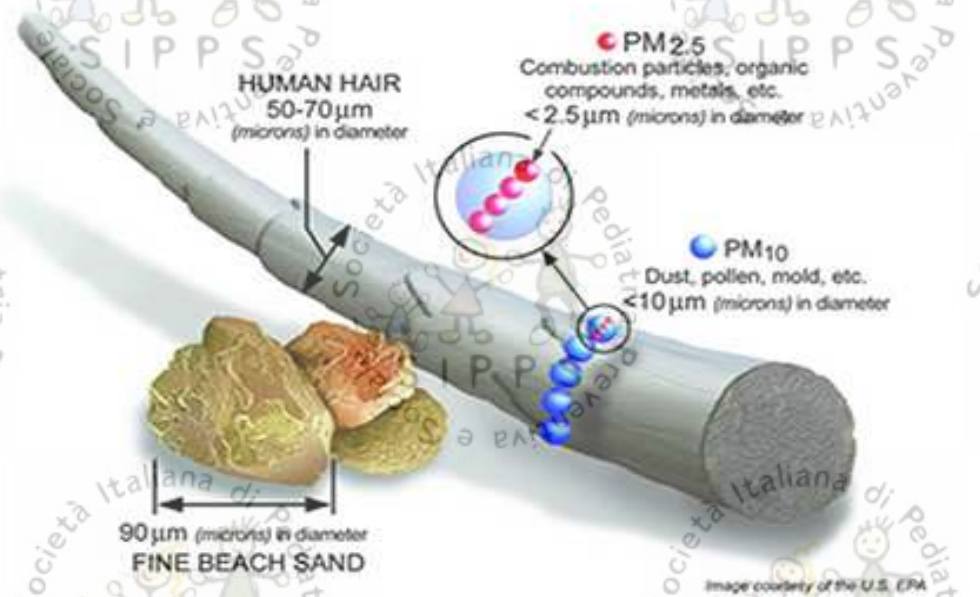
## Children whose mothers smoke:

- **70%** more respiratory problems
- Pneumonia and hospitalization in year 1 is **38%** higher
- Infant mortality is **80%** higher
- **20%** of all infant deaths could be avoided if all pregnant smokers stopped by the 16th week of gestation



## House dust mites

- House dust mites produce *Der p1* allergen, a potent sensitizer
- Good evidence of increased risk of sensitization with increasing allergen exposure, but this does not necessarily lead to asthma
- Small reductions in exposure will not necessarily lead to reduced incidence and/or symptoms
- Indoor humidity is important



# Living near a freeway, based on the location of the birth, and third trimester address, and autism

PM2.5, PM10, and NO2 at residences were higher in children with autism.

The magnitude of these **associations** appear to be **most pronounced during late gestation** (OR=1.98, 95%CI 1.20–3.31) **and early life / first year of life** (OR=1.98, 95%CI 1.20–3.31)

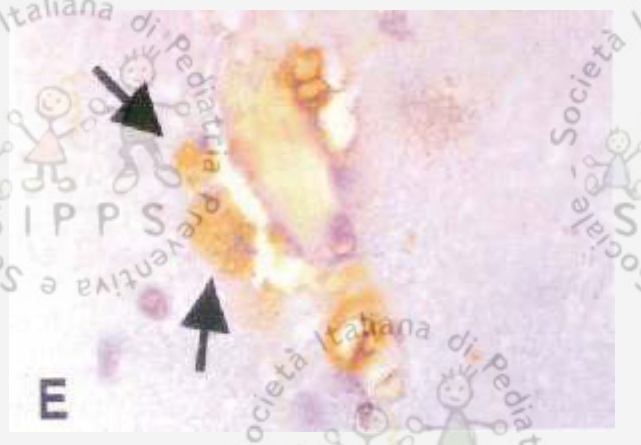
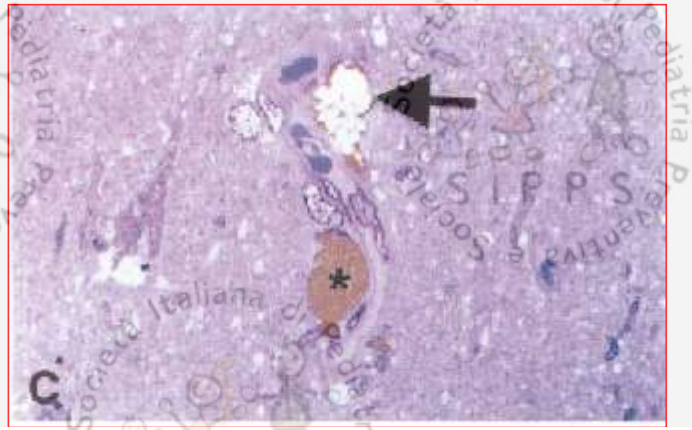
## Air Pollution and Brain Damage

Lilian Calderón-Garcidueñas, Biagio Azzarelli, Hilda Acuna, Raquel Garcia, Todd M. Gambling, Norma Osnaya, Sylvia Monroy, Maria Del Rosario Tizapantz, Johnny L. Carson, Anna Villarreal-Calderon and Barry Rewcastle

*Toxicol Pathol* 2002; 30; 373
DOI: [redacted]252929954

Exposure to complex mixtures of air pollutants produces inflammation in the upper and lower respiratory tract. Because the nasal cavity is a common portal of entry, respiratory and olfactory epithelia are vulnerable targets for toxicological damage. This study has evaluated, by light and electron microscopy and immunohistochemical expression of nuclear factor-kappa beta (NF-κB) and inducible nitric oxide synthase (iNOS), the olfactory and respiratory nasal mucosae, olfactory bulb, and cortical and subcortical structures from 32 healthy mongrel canine residents in Southwest Metropolitan Mexico City (SWMMC), a highly polluted urban region. Findings were compared to those in 8 dogs from Tlaxcala, a less polluted, control city. In SWMMC dogs, expression of nuclear neuronal NF-κB and iNOS in cortical endothelial cells occurred at ages 2 and 4 weeks; subsequent damage included alterations of the blood–brain barrier (BBB), degenerating cortical neurons, apoptotic glial white matter cells, deposition of apolipoprotein E (apoE)-positive lipid droplets in smooth muscle cells and pericytes, nonneuritic plaques, and neurofibrillary tangles. Persistent pulmonary inflammation and deteriorating olfactory and respiratory barriers may play a role in the neuropathology observed in the brains of these highly exposed canines. Neurodegenerative disorders such as Alzheimer's may begin early in life with air pollutants playing a crucial role.





And **a similar condition** has been **documented in the brain of young people dead for accidental causes..**

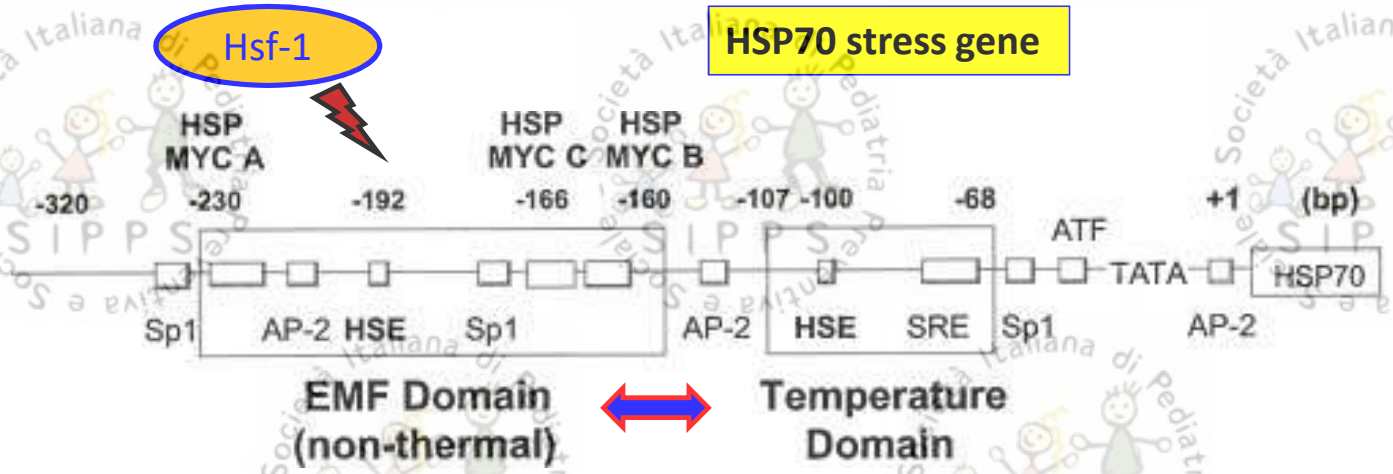
# Electromagnetic Fields, Pulsed Radiofrequency Radiation, and Epigenetics: How Wireless Technologies May Affect Childhood Development

Cindy Sage
*Sage Associates*

Ernesto Burgio
*International Society of Doctors for Environment (ISDE) Scientific Office*

Mobile phones and other wireless devices that produce electromagnetic fields (EMF) and pulsed radiofrequency radiation (RFR) are widely documented to cause potentially harmful health impacts that can be detrimental to young people. New epigenetic studies are profiled in this review to account for some neurodevelopmental and neurobehavioral changes due to exposure to wireless technologies. Symptoms of retarded memory, learning, cognition, attention, and behavioral problems have been reported in numerous studies and are similarly manifested in autism and attention deficit hyperactivity disorders, as a result of EMF and RFR exposures where both epigenetic drivers and genetic (DNA) damage are likely contributors. Technology benefits can be realized by adopting wired devices for education to avoid health risk and promote academic achievement.

**Specific DNA sequences on the promoter of the HSP70 stress gene are responsive to EMF...**



Synthesis of this stress protein is initiated in a **region of the promoter** where a transcription factor known as **Heat Shock Factor 1 (HSF-1) binds to a Heat Shock Element (HSE).**

The **EMF sensitive region on HSP70 promoter** is **upstream from the thermal domain of the promoter and is not sensitive to increased temperature**. The binding of **HSF-1** to **HSE** occurs at **–192** in the **HSP70 promoter** relative to the transcription initiation site.

The **EMF domain contains three nCTCTn myc-binding sites –230, –166 and –160 relative to the transcription initiation site and upstream of the binding sites for the heat shock (nGAAn)** and serum responsive elements…. **The electromagnetic response elements (EMREs) have also been identified on the c-*myc* promoter and are also responsive to EMF**

# Effects of a hypomagnetic field on DNA methylation during the differentiation of embryonic stem cells

Soonbong Baek[1], Hwan Choi[1], Hanseul Park[1], Byunguk Cho[1], Siyoung Kim[1] & Jongpil Kim[1,2]

It has been reported that hypomagnetic fields (HMFs) have a negative influence on mammalian physiological functions. We previously reported that HMFs were detrimental to cell fate changes during reprogramming into pluripotency. These studies led us to investigate whether HMFs affect cell fate determination during direct differentiation. Here, we found that an HMF environment attenuates differentiation capacity and is detrimental to cell fate changes during the *in vitro* differentiation of embryonic stem cells (ESCs). Moreover, HMF conditions cause abnormal DNA methylation through the dysregulation of DNA methyltransferase3b (Dnmt3b) expression, eventually resulting in incomplete DNA methylation during differentiation. Taken together, these results suggest that an appropriate electromagnetic field (EMF) environment may be essential for favorable epigenetic remodeling during cell fate determination via differentiation.

# Weak magnetic fields alter stem cell–mediated growth

Alanna V. Van Huizen[1], Jacob M. Morton[1], Luke J. Kinsey[1], Donald G. Von Kannon[1], Marwa A. Saad[1], Taylor R. Birkholz[1], Jordan M. Czajka[1], Julian Cyrus[2], Frank S. Barnes[2], Wendy S. Beane[1]*

Biological systems are constantly exposed to electromagnetic fields (EMFs) in the form of natural geomagnetic fields and EMFs emitted from technology. While strong magnetic fields are known to change chemical reaction rates and free radical concentrations, the debate remains about whether static weak magnetic fields (WMFs; <1 mT) also produce biological effects. Using the planarian regeneration model, we show that WMFs altered stem cell proliferation and subsequent differentiation via changes in reactive oxygen species (ROS) accumulation and downstream heat shock protein 70 (Hsp70) expression. These data reveal that on the basis of field strength, WMF exposure can increase or decrease new tissue formation in vivo, suggesting WMFs as a potential therapeutic tool to manipulate mitotic activity.

**Campi magnetici statici deboli (WMF <1 mT)** producono **alterazioni della proliferazione delle cellule staminali e della successiva differenziazione** attraverso cambiamenti nell'**accumulo di specie reattive dell'ossigeno (ROS)** e nell'**espressione della proteina di shock termico 70 (Hsp70)**.

Questi dati rivelano che sulla base della forza del campo, l'esposizione al WMF può aumentare o diminuire la **formazione di nuovo tessuto *in vivo*...**

VOLUME 12 | NUMBER 3 | MARCH 2009 NATURE NEUROSCIENCE

Maternal care influences hypothalamic-pituitary-adrenal (HPA) function in the rat through epigenetic programming of glucocorticoid receptor expression. In humans, childhood abuse alters HPA stress responses and increases the risk of suicide. We examined epigenetic differences in a neuron-specific glucocorticoid receptor (*NR3C1*) promoter between postmortem hippocampus obtained from suicide victims with a history of childhood abuse and those from either suicide victims with no childhood abuse or controls. We found decreased levels of glucocorticoid receptor mRNA, as well as mRNA transcripts bearing th glucocorticoid receptor $1_F$ splice variant and increased cytosine methylation of an *NR3C1* promoter. Patch-methylated *NR3C1* promoter constructs that mimicked the methylation state in samples from abused suicide victims showed decreased NGFI-A transcription factor binding and NGFI-A–inducible gene transcription. These findings translate previous results from rat to human and suggest a common effect of parental care on the epigenetic regulation of hippocampal glucocorticoid receptor expression.

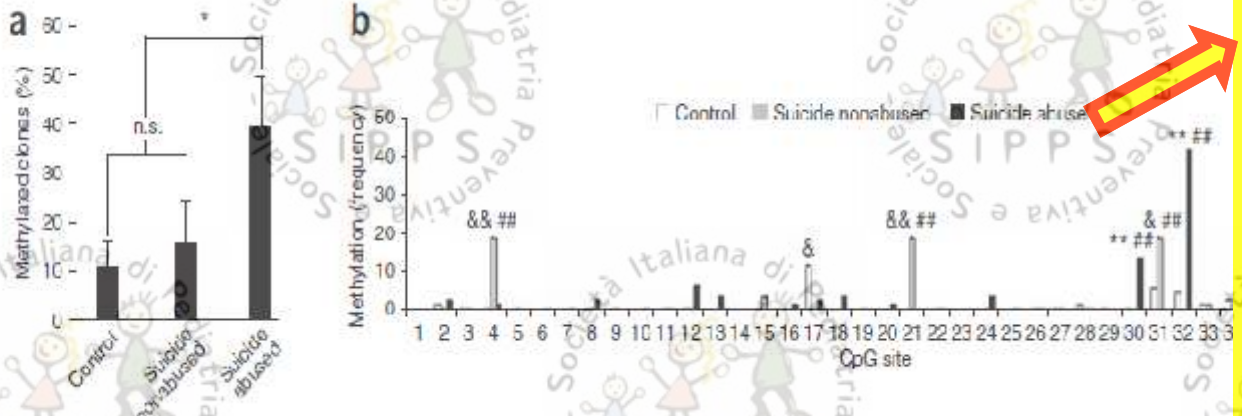

Figure 2 Methylation of the *NR3C1* promoter in the hippocampus. Twenty clones were sequenced for each subject for methylation mapp percentage of methylated clones for suicide victims with a history of childhood abuse ($n = 12$), suicide victims without a history of child and controls ($n = 12$). The methylation percentage was calculated as the number of clones with at least one methylated CpG site divide number of clones (* indicates $P \leq 0.05$; n.s. indicates not statistically significant). (b) Methylation of the *NR3C1* promoter region, show of methylation observed at each CpG site for suicide victims with a history of childhood abuse, suicide victims with no history of childho control subjects (*$P < 0.05$, **$P < 0.001$, abused suicides versus controls; $^{\&}P < 0.05$, $^{\&\&}P < 0.001$, non-abused suicides versus co $^{\#\#}P < 0.001$, abused suicides versus non-abused suicides; Bonferroni *post hoc* comparisons).

**Maternal care influences the programming** of the hypothalamic-pituitary-adrenal Axis (**HPA**) through epigenetic programming of ***glucocorticoid receptors expression***...

We found a **greatly increased methylation of cytosine in the promoter of a gene** codifying for a Glucocorticoids-Neuro-Receptor (NR3C1) **in the hippocampus of suicide victims with a history of childhood abuse** .. (post-mortem examinations)

# Association of Maternal Exposure to Childhood Abuse With Elevated Risk for Autism in Offspring

*Andrea L. Roberts, PhD; Kristen Lyall, ScD; Janet W. Rich-Edwards, ScD; Alberto Ascherio, DrPH; Marc G. Weisskopf, PhD, ScD*

*JAMA Psychiatry. 2013;70(5):508-515. Published online March 20, 2013. doi:10.1001/jamapsychiatry.2013.447*

**Importance:** Adverse perinatal circumstances have been associated with increased risk for autism in offspring. Women exposed to childhood abuse experience more adverse perinatal circumstances than women unexposed, but whether maternal abuse is associated with autism in offspring is unknown.

**Design and Setting:** Nurses' Health Study II, a population-based longitudinal cohort of 116 430 women.

**Conclusions and Relevance:** We identify an intergenerational association between maternal exposure to childhood abuse and risk for autism in the subsequent generation. Adverse perinatal circumstances accounted for only a small portion of this increased risk.

Another **transgenerational effect**, is based **on a broad longitudinal cohort study *(Nurses' Health Study II)*** which **identified maternal exposure to abuse in early childhood (!!)** as a risk factor for having a child with autism **e (Nurses 'Health Study II)**

# Epigenetic Transmission of Holocaust Trauma: Can Nightmares Be Inherited?

Natan P.F. Kellermann

*AMCHA, the National Israeli Center for Psychosocial Support of Survivors of the Holocaust and the Second Generation, Jerusalem, Israel*

The Holocaust left its visible and invisible marks not only on the survivors, but also on their children. Instead of numbers tattooed on their forearms, however, they may have been marked epigenetically with a chemical coating upon their chromosomes, which would represent a kind of biological memory of what the parents experienced. As a result, some suffer from a general vulnerability to stress while others are more resilient. Previous research assumed that such transmission was caused by environmental factors, such as the parents' child-rearing behavior. New research, however, indicates that these transgenerational effects may have been also (epi) genetically transmitted to their children. Integrating both hereditary and environmental factors, epigenetics adds a new and more comprehensive psychobiological dimension to the explanation of transgenerational transmission of trauma. Specifically, epigenetics may explain why latent transmission becomes manifest under stress. A general theoretical overview of epigenetics and its relevance to research on trauma transmission is presented.

The **Holocaust** left its **visible and invisible marks** not only on the survivors, but also on their **children**. Instead of **numbers tattooed on their forearms**, however, they may have been **marked epigenetically with a chemical coating upon their chromosomes**, which would represent a kind of biological memory of what the parents experienced.

# Holocaust Exposure and Intergenerational *FKBP5* Methylation

Childhood Adversity Effects on FKBP5 Intron 7 Methylation in Offspring

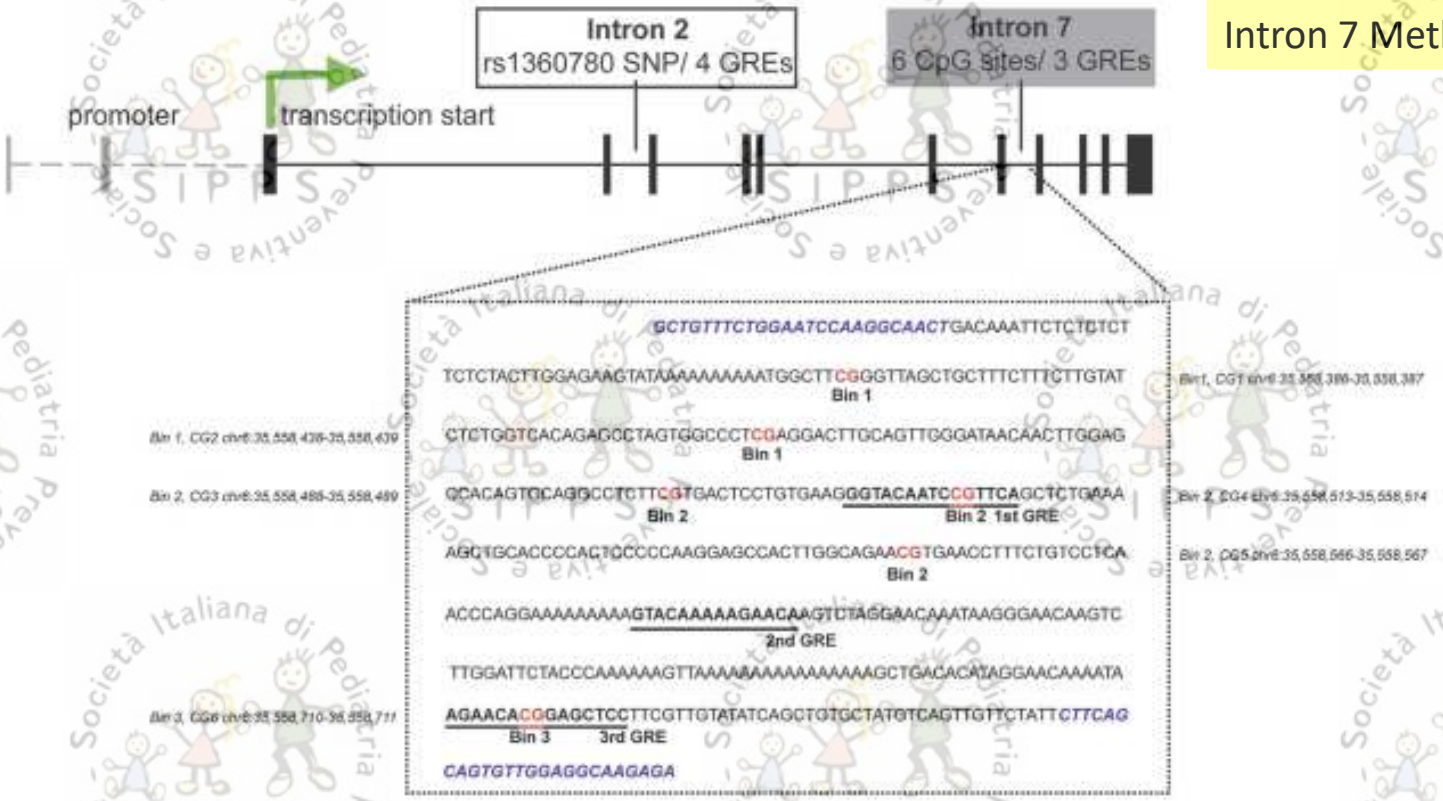

**Figure 1.** Schematic representation of the human *FKBP5* locus with intron 7 glucocorticoid receptor binding sequence investigated in this study. The upper panel depicts the *FKBP5* locus in 5′-3′ orientation. Black bars represent the 11 exons. The transcription start site is highlighted in green. The lower panel represents the intron 7 amplicon (476 base pair) chosen for DNA methylation analysis (primer sequence dark blue/italicized). Since pyrosequencing can only reliably generate short reads, the six cytosine-phosphate-guanine (CpG) sites (red) analyzed in three bins based on the proximity to three consensus glucocorticoid response elements (GREs) are represented in bold/underlined [pyrosequencing primers are described in Klengel *et al.* (35)]. The two CpGs of bin 1 were upstream of all GREs, the three CpGs of bin 2 are surrounding the first GRE, and bin 3 represents the CpG within the third GRE. The chromosomal position (hg19) of the CpG sites is indicated on the left and the right of the lower panel. SNP, single nucleotide polymorphism.

Review

# A 21st century view of evolution: genome system architecture, repetitive DNA, and natural genetic engineering

James A. Shapiro

*Department of Biochemistry and Molecular Biology, University of Chicago, 920 E. 58th Street, Chicago, IL 60637, United States*

The last 50 years of molecular genetics have produced an abundance of new discoveries and data that make it useful to revisit some basic concepts and assumptions in our thinking about genomes and evolution. Chief among these observations are the complex modularity of genome organization, the biological ubiquity of mobile and repetitive DNA sequences, and the fundamental importance of DNA rearrangements in the evolution of sequenced genomes. This review will take a broad overview of these developments and suggest some new ways of thinking about genomes as sophisticated informatic storage systems and about evolution as a systems engineering process.

# Somatic mutation in single human neurons tracks developmental and transcriptional history

Michael A. Lodato,[1*] Mollie B. Woodworth,[1*] Semin Lee,[2*] Gilad D. Evrony,[1] Bhaven K. Mehta,[1] Amir Karger,[3] Soohyun Lee,[2] Thomas W. Chittenden,[3,4†] Alissa M. D'Gama,[1] Xuyu Cai,[1‡] Lovelace J. Luquette,[2] Eunjung Lee,[2,5] Peter J. Park,[2,5§] Christopher A. Walsh[1§]

Neurons live for decades in a postmitotic state, their genomes susceptible to DNA damage. Here we survey the landscape of somatic single-nucleotide variants (SNVs) in the human brain. We identified thousands of somatic SNVs by single-cell sequencing of 36 neurons from the cerebral cortex of three normal individuals. Unlike germline and cancer SNVs, which are often caused by errors in DNA replication, neuronal mutations appear to reflect damage during active transcription. Somatic mutations create nested lineage trees, allowing them to be dated relative to developmental landmarks and revealing a polyclonal architecture of the human cerebral cortex. Thus, somatic mutations in the brain represent a durable and ongoing record of neuronal life history, from development through postmitotic function.

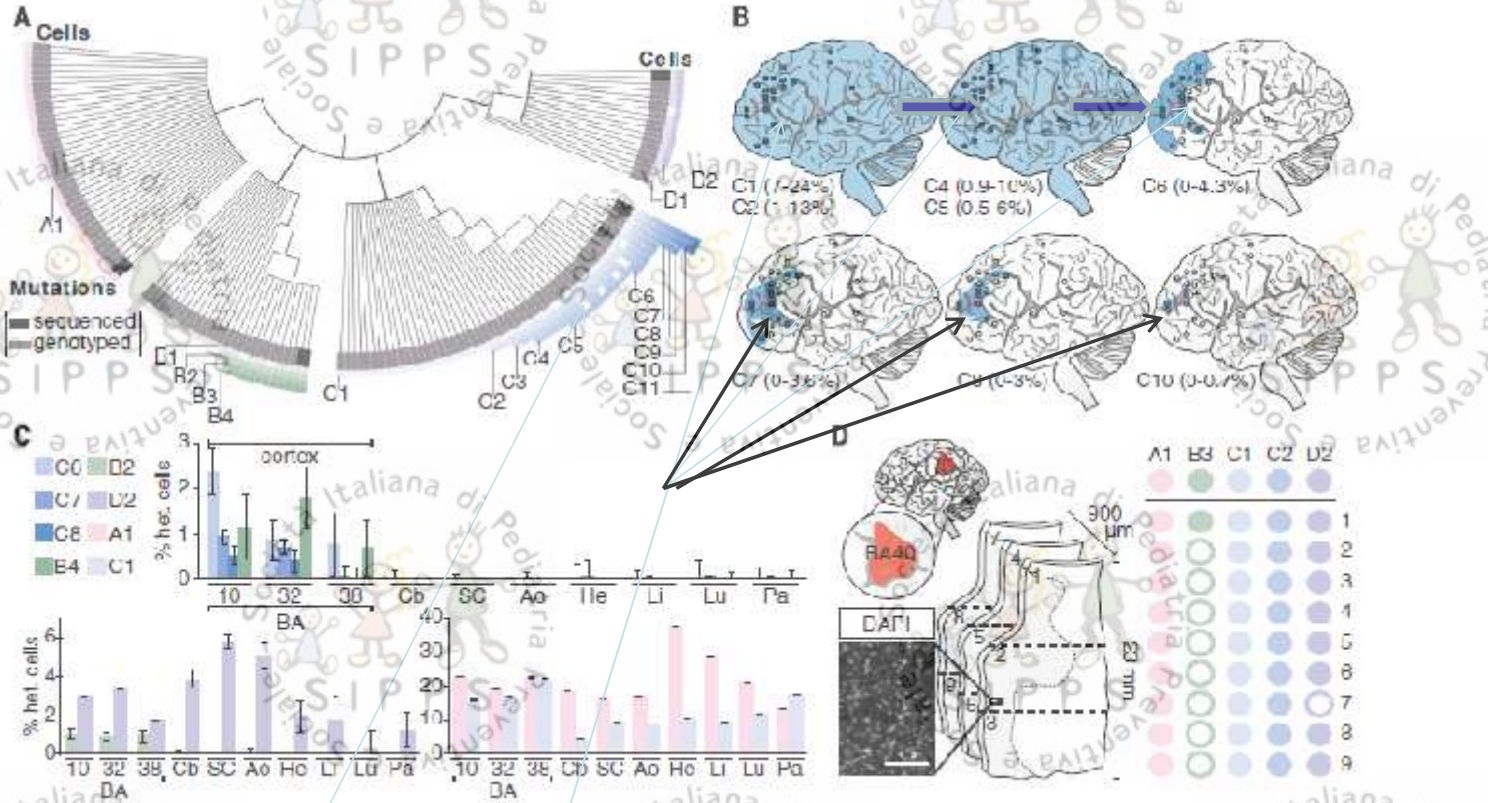

**Fig. 3. Somatic mutations are shared between multiple neurons and demonstrate lineage relationships.** (**A**) Lineage map of 135 human cortical neurons from brain B derived from 19 clonal somatic mutations, including SNVs, long interspersed nuclear element (LINE) insertions, and a TC dinucleotide expansion. Neurons are placed into four distinct nested clades (pink, green, blue, purple) defined by one or more independent mutations. Cells are ordered within clades according to the presence of multiple somatic mutations. A few cells in each clade fail to manifest individual SNVs shared by other cells of the same clade (indicated by open squares), likely representing incomplete amplification (fig. S2). Dark gray boxes represent cells analyzed by WGS; light gray represents cells analyzed by Sanger-based genotyping. Genomic locations of somatic mutations are given in fig. S11. (**B**) Ultradeep sequencing of mutated loci across the cortex of brain B. Clonal SNVs from a single clade are progressively regionally restricted to frontal cortex and become progressively rarer in bulk tissue, reflecting their later origin during development and neurogenesis. Blue circle, mutation present, empty circle, mutation absent, blue shading, likely spatial distribution of mutation. Percentage range of heterozygous cells is indicated for each SNV. (**C**) Ultradeep sequencing of mutated loci across the brain and body. Some variants are brain specific (top) and others are shared across germ layers (bottom). Samples sequenced are prefrontal cortex [Brodmann area (BA) 10/BA46], cingulate cortex (BA32/BA8), temporal cortex (BA38), cerebellum (Cb), spinal cord (SC), aorta (Ao), heart (He), liver (Li), lung (Lu), and pancreas (Pa). (**D**) Genotyping shared variants in small sections of human cortex. Left: 4′,6-diamidino-2-phenylindole (DAPI) stain of segment of representative section; scale bar, 200 µm. Center: Three consecutive 300-µm coronal sections from BA40 (red, upper left) were dissected into three axial regions each (1 to 9). Right: Genotyping results for dissected sections. Solid circles denote presence of mutation in indicated sample; open circles denote absence. Mutations with high allele fractions are present in all or virtually all regions, whereas only the least prevalent somatic variant (present in <0.5% of cells) is present in one region but not most regions.

Double-strand break repair is required for neural development, and brain cells contain somatic genomic variations. Now, Wei et al. demonstrate that neural stem and progenitor cells undergo very frequent DNA breaks in a very restricted set of genes involved in neural cell adhesion and synapse function.

Many of the identified genes are **expressed in NSPCs located in the brain regions responsible for higher functions such as short-term learning,** and mutations in these genes in humans are associated with (and maybe predispose to) **psychiatric and neurological disorders manifested in mind functions—autism, manic depressive and depressive disorders, schizophrenia**, and others

## In Brief

Neural stem and progenitor cells undergo massive genomic alterations in a very restricted set of genes involved in synapse function and neural cell adhesion, processes that are likely to govern the special behavior of brain cells. Many of these genes have also been implicated in mental disorders.

## Highlights

1) **27 Recurrent DSB clusters (RDCs)** are identified **in neural stem/progenitor cells**

**2) All RDCs are within genes**, most of which are long, transcribed, and late replicating

3) Most RDC genes are **involved in synapse function and/or neural cell adhesion**

**4)** A nucleotide-resolution view of **replication stress-associated fragile sites** is provided

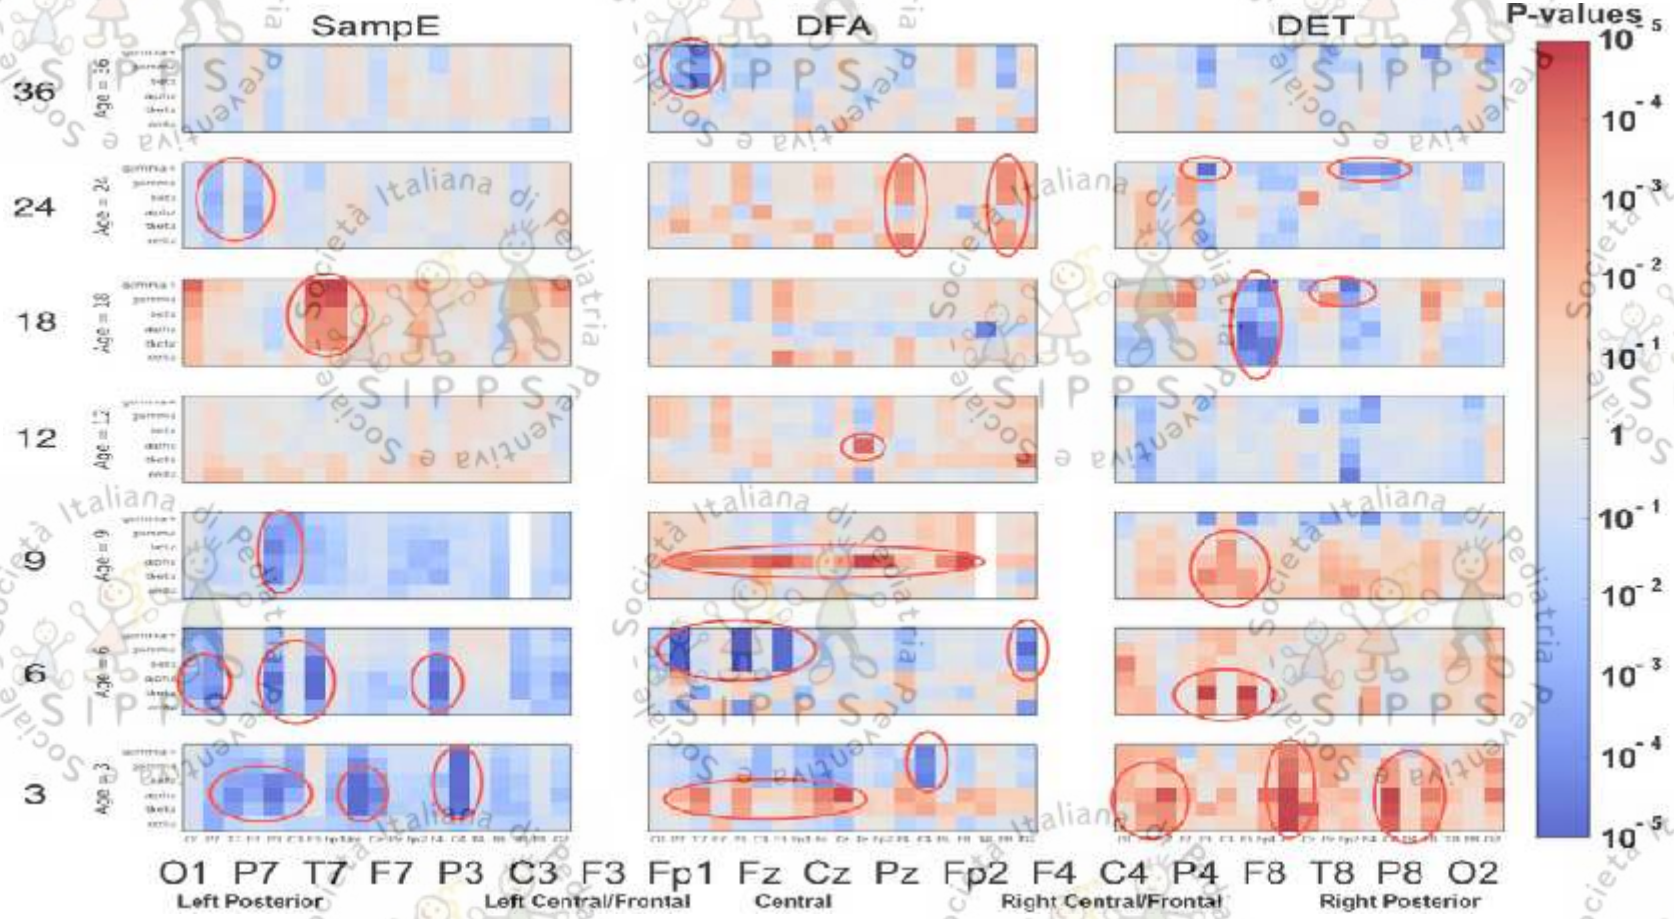
# EEG Analytics for Early Detection of Autism Spectrum Disorder: A data-driven approach

Received: 15 August 2017
Accepted: 28 March 2018
Published online: 01 May 2018

William J. Bosl[1,2,3], Helen Tager-Flusberg[4] & Charles A. Nelson[1,2,5]

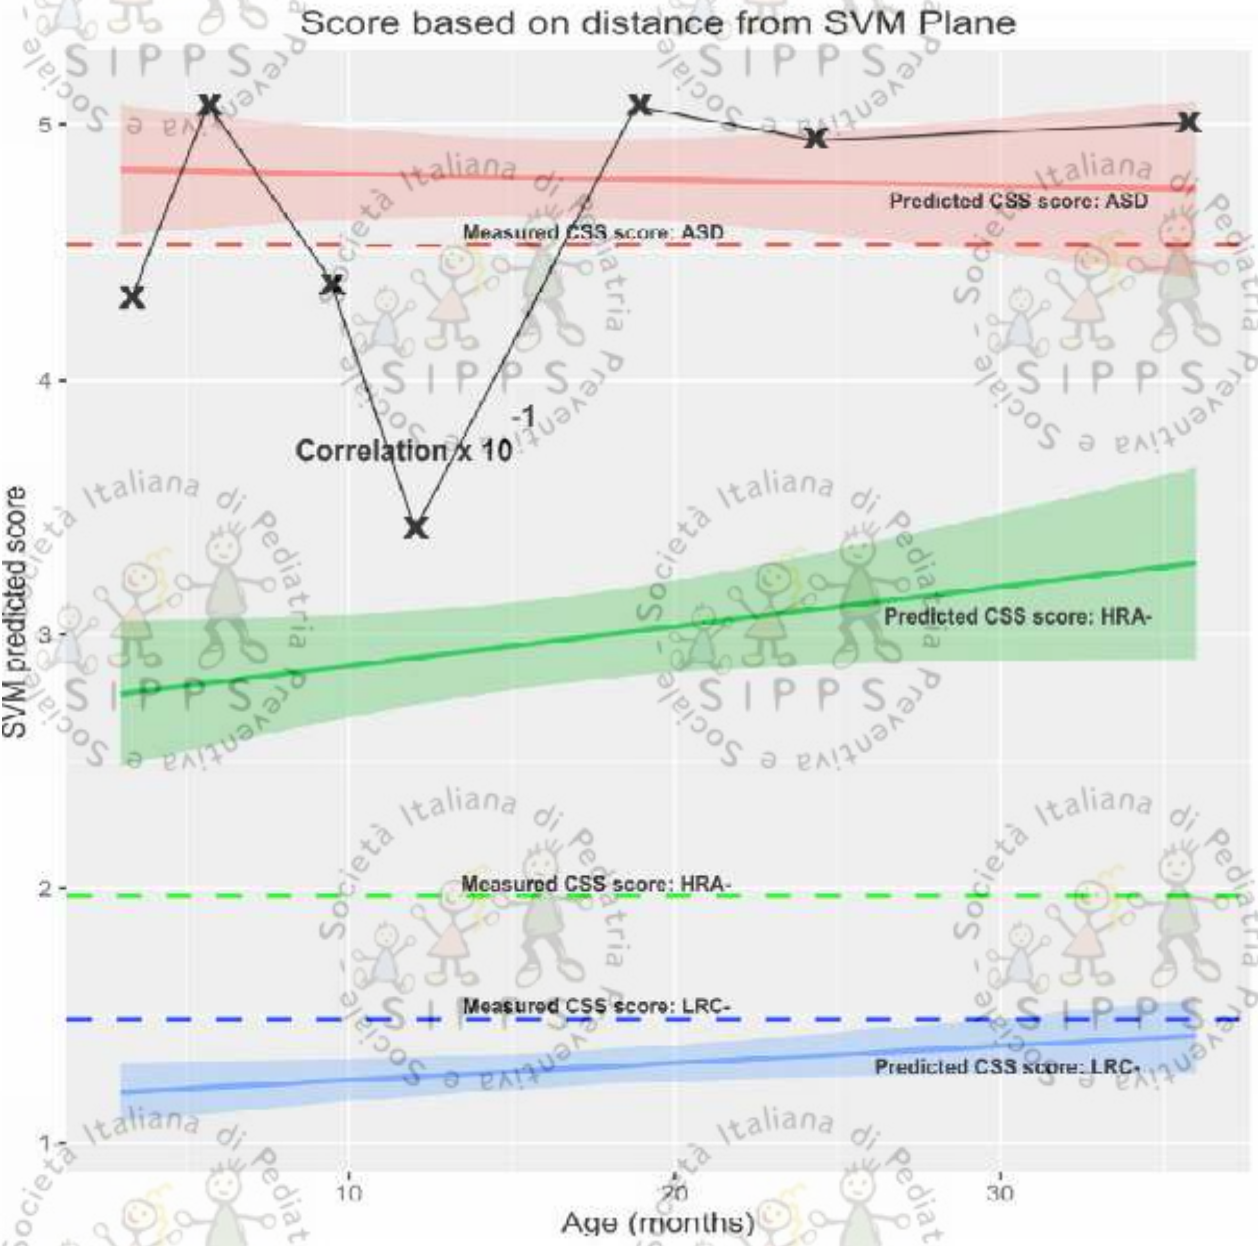
Autism spectrum disorder (ASD) is a complex and heterogeneous disorder, diagnosed on the basis of behavioral symptoms during the second year of life or later. Finding scalable biomarkers for early detection is challenging because of the variability in presentation of the disorder and the need for simple measurements that could be implemented routinely during well-baby checkups. EEG is a relatively easy-to-use, low cost brain measurement tool that is being increasingly explored as a potential clinical tool for monitoring atypical brain development. EEG measurements were collected from 99 infants with an older sibling diagnosed with ASD, and 89 low risk controls, beginning at 3 months of age and continuing until 36 months of age. Nonlinear features were computed from EEG signals and used as input to statistical learning methods. Prediction of the clinical diagnostic outcome of ASD or not ASD was highly accurate when using EEG measurements from as early as 3 months of age. Specificity, sensitivity and PPV were high, exceeding 95% at some ages. Prediction of ADOS calibrated severity scores for all infants in the study using only EEG data taken as early as 3 months of age was strongly correlated with the actual measured scores. This suggests that useful digital biomarkers might be extracted from EEG measurements.

L'autismo è difficile da diagnosticare, soprattutto all'inizio della vita. Un nuovo studio su *Scientific Reports* mostra che **EEG** (oltretutto poco costosi) **predicono accuratamente o escludono il disturbo dello spettro autistico (ASD) in neonati di appena 3 mesi**.



Gli **algoritmi computazionali hanno analizzato sei diverse componenti (frequenze) dell'EEG (high gamma, gamma, beta, alpha, theta, delta) usando una varietà di misure di complessità del segnale**.

Queste misure **possono riflettere le differenze nel modo in cui il cervello è cablato e in che modo elabora e integra le informazioni**



I risultati sono stati sorprendenti.. **l'accuratezza predittiva a 9 mesi è stata quasi del 100%,** inoltre si è potuto **prevedere la gravità dell'ASD,** come indicato dal punteggio di gravità calibrato ADOS..

Le **differenze precoci di complessità del segnale**, mostrano **molteplici aspetti dell'attività cerebrale**, e corrispondano all'idea che **l'autismo sia un disturbo che inizia durante lo sviluppo precoce del cervello,** ma può assumere **diverse traiettorie**.

# The "MS-ROM/IFAST" Model, a Novel Parallel Nonlinear EEG Analysis Technique, Distinguishes ASD Subjects From Children Affected With Other Neuropsychiatric Disorders With High Degree of Accuracy

## Abstract

*Background and Objective.* In a previous study, we showed a new EEG processing methodology called Multi-Scale Ranked Organizing Map/Implicit Function As Squashing Time (MS-ROM/IFAST) performing an almost perfect distinction between computerized EEG of Italian children with autism spectrum disorder (ASD) and typically developing children. In this study, we assessed this system in distinguishing ASD subjects from children affected with other neuropsychiatric disorders (NPD). *Methods.* At a psychiatric practice in Texas, 20 children diagnosed with ASD and 20 children diagnosed with NPD were entered into the study. Continuous segments of artifact free EEG data lasting 10 minutes were entered in MS-ROM/IFAST. From the new variables created by MS-ROM/IFAST, only 12 has been selected according to a correlation criterion. The selected features represent the input on which supervised machine learning systems (MLS) acted as blind classifiers. *Results.* The overall predictive capability in distinguishing ASD from other NPD cases ranged from 93% to 97.5%. The results were confirmed in further experiments in which Italian and US data have been combined. In this analysis, the best MLS reached 95.0% global accuracy in 1 out of 3 classes distinction (ASD, NPD, controls). This study demonstrates the value of EEG processing with advanced MLS in the differential diagnosis between ASD and NPD cases. The results were not affected by age, ethnicity and technicalities of EEG acquisition, confirming the existence of a specific EEG signature in ASD cases. To further support these findings, it was decided to test the behavior of already trained neural networks on 10 Italian very young ASD children (25-37 months). In this test, 9 out of 10 cases have been correctly recognized as ASD subjects in the best case. *Conclusions.* These results confirm the possibility of an early automatic autism detection based on standard EEG.
